

A Brief Conversation About Java

The Java language is a language of simple understanding that allows the developer to perform an excellent job. In my opinion and I believe that in the opinion of many too, Java has a strong point which is its JVM (Java Virtual Machine) that makes the work of a developer, so to speak easier. Why? I will explain in a way that even lay people can understand.

Let's imagine the following situation, a company that has many customers and those customers have different systems or work methodologies. How do you do to serve them? The most logical thing would be to prepare a good customer relationship team that would interact and translate the various methodologies for the understanding of other employees, that is, these employees would have the function of intermediating and interpreting the requirements and in turn assisting in the customization of the project, without having to change your company's methodology.

Were you able to identify the principle? The idea is similar, when you develop a Java program it will be possible to use that program on computers that have installed the JVM, that is to say, that the JVM already comes with the language pack when it is downloaded. So, avoid the inconvenience of having to adapt your system to each system. Imagine bringing this to greater proportions. For example, a technology company has around two thousand customers who have different operating systems, imagine if the programmer had to adapt the language to run the program he developed or have to install each customer's operating system to develop some program. In fact, this situation would be and is not feasible, so we can say that Java is a good language to work with, as the programmer will only be concerned with the systems and business requirements to be met, generating greater concentration and quality in software development.
